1 **Abstract**

2 Population viscosity, *i.e.*, low emigration out of the natal deme, leads to high
3 within-deme relatedness, which is beneficial to the evolution of altruistic behav-
4 ior when social interactions take place among deme-mates. However, a detri-
5 mental side-effect of low emigration is the increase in competition among re-
6 lated individuals. The evolution of altruism depends on the balance between
7 these opposite effects. This balance is already known to be affected by details
8 of the life-cycle; we show here that it further depends on the fidelity of strategy
9 transmission from parents to their offspring. We consider different life-cycles
10 and identify thresholds of parent-offspring strategy transmission inaccuracy, above
11 which higher emigration can increase the frequency of altruists maintained in
12 the population. **EXPLAIN RESULT** Predictions were first obtained analytically
13 assuming weak selection and equal deme sizes, then confirmed with stochastic
14 simulations relaxing these assumptions. This result challenges the notion that
15 the evolution of altruism **REMOVE REQUIRE** requires limited dispersal.

16 **Introduction**

17 In his pioneering work on the evolution of social behavior, Hamilton suggested
18 that altruistic behavior would be associated to limited dispersal (Hamilton, 1964,
19 p. 10). This notion, that tighter links between individuals are beneficial to the
20 evolution of altruism, has been shown to hold in a number of population struc-
21 tures (see *e.g.* Ohtsuki et al., 2006; Taylor et al., 2007a; Lehmann et al., 2007; Allen
22 et al., 2017). The rationale is that altruism is favored when altruists interact
23 more with altruists than defectors do (Hamilton, 1975, p. 141; Fletcher & Doe-
24 beli, 2009), a condition that is met in viscous populations, *i.e.*, populations with
25 limited dispersal.

26 Yet, living next to your kin also implies competing against them (West et al.,
27 2002), which is detrimental to the evolution of altruism. The evolution of so-
28 cial traits hence depends on the balance between the positive effects of inter-
29 actions with related individuals and the detrimental consequences of kin com-
30 petition. Under specific conditions, the two effects can even compensate each
31 other, thereby annihilating the impact of population viscosity on the evolution
32 of altruism. First identified with computer simulations (Wilson et al., 1992), this
33 cancellation result was analyzed by Taylor (1992a) in a model with synchronous
34 generations (*i.e.*, Wright-Fisher model) and a subdivided population of constant,
35 infinite size. The cancellation result was later extended to heterogeneous pop-
36 ulations (Rodrigues & Gardner, 2012, with synchronous generations and infinite
37 population size), and other life-cycles, with generic regular population struc-
38 tures (Taylor et al., 2011, with synchronous generations but also with continuous
39 generations and Birth-Death updating). However, small changes in the model's
40 assumptions, such as overlapping generations (Taylor & Irwin, 2000) or the pres-
41 ence of empty sites (Alizon & Taylor, 2008) can tip the balance in the favor of al-
42 truism. This high dependence on life-cycle specificities highlights the difficulty
43 of making general statements about the role of spatial structure on the evolution

44 of altruism. In this study, we will consider three different life-cycles: Wright-
45 Fisher, where the whole population is renewed at each time step, and two Moran
46 life-cycles (Birth-Death and Death-Birth), where a single individual dies and is
47 replaced at each time step. These life-cycles are classically used in studies on
48 altruism in structured populations. Even though they differ by seemingly minor
49 details, they are known to have very different outcomes in models with perfect
50 parent-offspring transmission (*e.g.*, Taylor, 1992a; Rousset, 2004; Ohtsuki et al.,
51 2006; Lehmann et al., 2007; Taylor, 2010).

52 A large number of studies on the evolution of social behavior consider simple
53 population structures (typically, homogeneous populations *sensu* Taylor et al.
54 (2007a)) and often also infinite population sizes (but see Allen et al., 2017, for
55 results on any structure). These studies also make use of weak selection approx-
56 imations, and commonly assume rare (*e.g.*, Leturque & Rousset, 2002; Taylor
57 et al., 2007b; Tarnita & Taylor, 2014) or absent mutation (for models assuming
58 infinite population sizes, or models concentrating on fixation probabilities; see
59 Lehmann & Rousset, 2014; Van Cleve, 2015, for recent reviews). These simplify-
60 ing assumptions are often a necessary step towards obtaining explicit analytical
61 results. Simple population structures (*e.g.*, regular graphs, or subdivided popu-
62 lations with demes of equal sizes) help reduce the dimensionality of the system
63 under study, in particular when the structure of the population displays sym-
64 metries such that all sites behave the same way in expectation. Weak selection
65 approximations are crucial for disentangling spatial moments (Lion, 2016), that
66 is, changes in global *vs.* local frequencies (though they can in some cases be re-
67 laxated, as in Mullan & Lehmann, 2014). Mutation, however, is usually ignored by
68 classical models of inclusive fitness because these models assume infinite pop-
69 ulation sizes, so that there is no need to add mechanisms that restore genetic
70 diversity (Tarnita & Taylor, 2014). In populations of finite size, this diversifying
71 effect can be obtained thanks to mutation.

72 When strategy transmission is purely genetic, it makes sense to assume that
73 mutation is relatively infrequent. Even in this case, though, mutations from “so-
74 cial” to “non-social” types cannot always be neglected. For instance, experi-
75 ments with the bacteria *Pseudomonas fluorescens* have identified transitions be-
76 tween populations dominated by the ancestral “solitary” Smooth Morph type
77 and mat-forming “social” Wrinkly Spreaders, that can be re-invaded by Smooth
78 Morphs not contributing to the formation of the mat (hence described as “cheaters”).
79 The transitions between the different types are due to spontaneous mutations
80 occurring over the timescale of the experiment (Hammerschmidt et al., 2014).
81 In addition to genetic transmission, a social strategy can also be culturally trans-
82 mitted from parent to offspring. In this case, “rebellion” (as in Frank’s Rebellious
83 Child Model (Frank, 1997)), *i.e.*, adopting a social strategy different from one’s
84 parents, does not have to be infrequent. Since it is known that imperfect strat-
85 egy transmission can alter the evolutionary dynamics of social traits, in particu-
86 lar in spatially structured populations (see *e.g.*, Allen et al., 2012; Débarre, 2017,
87 for graph-structured populations), it is therefore important to understand the
88 impact of imperfect strategy transmission on the evolution of social behavior.

89 Here, we want to explore the consequences of imperfect strategy transmis-
90 sion from parents to their offspring on the evolution of altruistic behavior in sub-
91 divided populations¹. The question was tackled by Frank (1997), but with a non
92 “fully dynamic model” (Frank, 1997, legend of Fig.7). Relatedness was treated
93 like a parameter, which precluded the exploration of the effects of population
94 viscosity on the evolution altruism.

95 For each of the three life-cycles that we consider, we compute the expected
96 (*i.e.*, long-term) frequency of altruists maintained in a subdivided population,
97 and investigate how this frequency is affected by mutation and emigration. We
98 find that, contrary to what happens with perfect strategy transmission, higher

¹Note that for the sake of concision, we use the word “mutation” throughout the paper, keeping in mind that strategy transmission does not have to be genetic.

99 emigration can increase the expected frequency of altruists in the population.

100 **Model and methods**

101 **Assumptions**

102 We consider a population of size N , subdivided into N_D demes connected by
 103 dispersal, each deme hosting exactly n individuals (*i.e.*, each deme contains n
 104 sites, each of which is occupied by exactly one individual; we have $nN_D = N$).
 105 Each site has a unique label i , $1 \leq i \leq N$. There are two types of individuals in
 106 the population, altruists and defectors. The type of the individual living at site i
 107 ($1 \leq i \leq N$) is given by an indicator variable X_i , equal to 1 if the individual is an
 108 altruist, and to 0 if it is a defector. The state of the entire population is given by
 109 a N -long vector \mathbf{X} . For a given population state \mathbf{X} , the proportion of altruists is
 110 $\bar{X} = \sum_{i=1}^N X_i$. All symbols are summarized in table A1.

111 Reproduction is asexual. The offspring of altruists are altruists themselves
 112 with probability $1 - \mu_{1 \rightarrow 0}$, and are defectors otherwise ($0 < \mu_{1 \rightarrow 0} \leq 1/2$). Similarly,
 113 the offspring of defectors are defectors with probability $1 - \mu_{0 \rightarrow 1}$, and are altruists
 114 otherwise ($0 < \mu_{0 \rightarrow 1} \leq 1/2$). Our calculations will be simpler if we introduce the
 115 following change of parameters:

{eq:changemut}

$$\nu = \frac{\mu_{0 \rightarrow 1}}{\mu_{1 \rightarrow 0} + \mu_{0 \rightarrow 1}} \quad (0 < \nu < 1), \text{ and} \quad (1a) \quad \text{{eq:nu}}$$

$$\mu = \mu_{1 \rightarrow 0} + \mu_{0 \rightarrow 1} \quad (0 < \mu \leq 1). \quad (1b) \quad \text{{eq:mu}}$$

116 The composite parameter ν corresponds to the expected frequency of altruists
 117 in the population at the mutation-drift balance (*i.e.*, in the absence of selection;
 118 see Appendix A for details). We call ν the “mutation bias” parameter. Parameter
 119 μ is the sum of the two mutation probabilities. In the absence of selection, at
 120 the mutation-drift equilibrium, the correlation between offspring type and their
 121 parent’s type is $1 - \mu$ (see Appendix A for details for the calculation). We call μ the

122 mutation intensity.

123 An individual of type X_k expresses a social phenotype $\phi_k = \delta X_k$, where δ
 124 is assumed to be small ($\delta \ll 1$). Social interactions take place within each deme,
 125 benefits are shared with the $n-1$ other deme-mates. We assume that social inter-
 126 actions affect individual fecundity; f_k denotes the fecundity of the individual at
 127 site k ($1 \leq k \leq N$). We denote by b the sum of the marginal effects of deme-mates'
 128 phenotypes on the fecundity of a focal individual, and by $-c$ the marginal effect
 129 of a focal individual's phenotype on its own fecundity ($c \leq b$; see system (A22) for
 130 formal definitions).

131 Offspring remain in the parental deme with probability $1 - m$ and land on
 132 any site of the parental deme with equal probability (including the very site of
 133 their parent). With probability m , offspring emigrate to a different deme, cho-
 134 sen uniformly at random among the $N_D - 1$ other demes. Denoting by d_{ij} the
 135 probability of moving from site i to site j , we have

$$d_{ij} = \begin{cases} d_{\text{in}} = \frac{1-m}{n} & \text{if both sites are in the same deme;} \\ d_{\text{out}} = \frac{m}{(N_D-1)n} & \text{if the two sites are in different demes,} \end{cases} \quad (2) \quad \{\text{eq: defD}\}$$

136 with $0 < m < 1 - \frac{1}{N_D}$. (This upper bound is here to ensure that within-deme
 137 relatedness R , which will be defined later in the article, remains positive.)

138 We denote by $B_i = B_i(\mathbf{X}, \delta)$ the expected number of successful offspring of the
 139 individual living at site i (successful means alive at the next time step), and by
 140 $D_i = D_i(\mathbf{X}, \delta)$ the probability that the individual living at site i dies. Both depend
 141 on the state of the population \mathbf{X} , but also on the way the population is updated
 142 from one time step to the next, *i.e.*, on the chosen life-cycle (also called updating
 143 rule). We also define

$$W_i := (1 - \mu)B_i + 1 - D_i; \quad (3) \quad \{\text{eq: defW}\}$$

144 this is a particular definition of fitness, where the number of offspring produced

145 (B_i) is scaled by the parent-offspring type correlation ($1 - \mu$).

146 We will specifically explore three different life-cycles. At the beginning of
147 each step of each life-cycle, all individuals produce offspring, that can be mu-
148 tated; then these juveniles move, within the parental deme or outside of it, and
149 land on a site. The next events occurring during the time step depend on the
150 life-cycle:

151 **Moran Birth-Death:** One of the newly created juveniles is chosen at random; it
152 kills the adult who was living at the site, and replaces it; all other juveniles
153 die.

154 **Moran Death-Birth:** One of the adults is chosen to die (uniformly at random
155 among all adults). It is replaced by one of the juveniles who had landed in
156 its site. All other juveniles die.

157 **Wright-Fisher:** All the adults die. At each site of the entire population, one of
158 the juveniles that landed there is chosen and establishes at the site.

159 With social interactions affecting individual fecundity, previous studies have shown
160 that altruism is disfavored under the Moran Birth-Death and Wright-Fisher life-
161 cycles, because the expected frequency of altruists under these life-cycles is lower
162 than what it would be in the absence of selection (*e.g.*, Taylor, 1992a, 2010; Taylor
163 et al., 2011; Débarre, 2017). However, we are interested in the actual value of the
164 expected proportion of altruists in the population, not just whether it is higher
165 or lower than the neutral expectation. This is why we are still considering the
166 Moran Birth-Death and Wright-Fisher life-cycles in this study.

167 **Methods**

168 **Analytical part**

169 The calculation steps to obtain the expected (*i.e.*, long-term) proportion of al-
170 truists are given in Appendix B. They go as follows: first, we write an equation for

171 the expected frequency of altruists in the population at time $t + 1$, conditional
 172 on the composition of the population at time t ; we then take the expectation of
 173 this quantity and consider large times t . After this, we write a first order expan-
 174 sion for phenotypic differences δ close to 0 (this corresponds to a weak selection
 175 approximation).

176 The formula involves quantities that can be identified as neutral probabil-
 177 ities of identity by descent Q_{ij} . These quantities correspond to the probability
 178 that individuals living at site i and j share a common ancestor and that no muta-
 179 tion occurred on either lineage since that ancestor, in a model with no selection
 180 ($\delta = 0$) and with mutation probability μ ; this is the “mutation definition” of iden-
 181 tity by descent (Rousset & Billiard, 2000). In a subdivided population like ours,
 182 there are three possible values of Q_{ij} :

$$Q_{ij} = \begin{cases} 1 & \text{when } i = j, \\ Q_{\text{in}} & \text{when } i \neq j \text{ and both sites are in the same deme,} \\ Q_{\text{out}} & \text{when both sites are in different demes.} \end{cases} \quad (4) \quad \{\text{eq:Q3}\}$$

183 These neutral probabilities of identity by descent depend on the chosen life-
 184 cycle, and are also computed by taking the long-term expectation of conditional
 185 expectations after one time step (see Appendix C.1 and C.2 and supplementary
 186 Mathematica file (Wolfram Research, Inc., 2017).)

187 **Stochastic simulations**

188 To check our results and also relax some key assumptions, we ran stochastic sim-
 189 ulations (coded in C). The simulations were run for 10^8 generations (one gener-
 190 ation is one time step for the Wright-Fisher life-cycle, and N time steps for the
 191 Moran life-cycles). For each set of parameters and life-cycle, using R (R Core
 192 Team, 2015), we estimated the long-term frequency of altruists by sampling the
 193 population every 10^3 generations and computing the average frequency of altru-

194 ists. All scripts are available at

195 <https://flodebarre.github.io/SocEvolSubdivPop/>

196 Results

197 Expected frequencies of altruists for each life-cycle

198 For each of the life-cycles that we consider, the expected frequency of altruists in
199 the population, $\mathbb{E}[\bar{X}]$, can be approximated as

$$\mathbb{E}[\bar{X}] \approx v + \frac{\delta}{\mu B^*} v(1-v)(1-Q_{\text{out}}) \times \left[\underbrace{\frac{\partial W}{\partial f_{\bullet}}(-c) + \frac{\partial W}{\partial f_{\text{in}}}b}_{-C} + \underbrace{\left(\frac{\partial W}{\partial f_{\bullet}}b + (n-1)\frac{\partial W}{\partial f_{\text{in}}}(-c) + (n-2)\frac{\partial W}{\partial f_{\text{in}}}b \right)}_{B} \underbrace{\frac{Q_{\text{in}} - Q_{\text{out}}}{1 - Q_{\text{out}}}}_R \right], \quad (5) \quad \{\text{eq:EXapprox}\}$$

200 with W as defined in eq. (3). Calculations leading to eq. (5) are presented in
201 Appendix B; notations are recapitulated in table A1. In particular, B^* is the ex-
202 pected number of offspring produced by an adult, in the absence of selection
203 (when $\delta = 0$; $B^* = 1$ for the Wright-Fisher life-cycle and $B^* = 1/N$ for the Moran
204 life-cycles). Subscript “•” denotes a focal individual itself, and “in” a deme-mate.

205 The expected frequency of altruists in the population is approximated, under
206 weak selection ($\delta \ll 1$), by the sum of what it would be in the absence of selec-
207 tion ($\mathbb{E}_0[\bar{X}] = v$, first term in eq. (5)), plus a deviation from this value, scaled by
208 δ . The $-C$ term corresponds to the effects of a change of a focal individual’s phe-
209 notype on its own fitness (with the fitness definition given in eq. (3)). The B term
210 corresponds to the sum of the effects of the change of deme-mates’ phenotypes
211 on an individual’s fitness. It is multiplied by R , which is relatedness.

212 The parametrization proposed in eq. (1) allows us to decouple the effects of
213 the two new mutation parameters, v and μ . The mutation bias v , which was
214 defined in eq. (1a), does not affect the sign of the second (“deviation”) term in
215 eq. (5); it only appears in the $v(1-v)$ product. The mutation intensity μ , however,

216 affects the values of W , Q_{in} and Q_{out} . The presence of μ at the denominator in
 217 eq. (5) may look ominous; however, both R and $(1 - Q_{\text{out}})/\mu$ have a finite limit
 218 when $\mu \rightarrow 0$.

219 The different terms depend on the chosen life-cycle. We first focus on relat-
 220 edness R .

221 **Relatedness R**

222 Within-deme relatedness depends on the number of individuals that are born
 223 at each time step, and hence on the chosen life-cycle. In a Moran life-cycle (de-
 224 noted by M), one individual is updated at each time step, while under a Wright-
 225 Fisher life-cycle (denoted by WF), N individuals – the whole population – are up-
 226 dated at each time step. The formulas for relatedness for any number of demes
 227 N_D and mutation intensity μ are presented in Appendix C.2 (eq. (A44) and eq. (A50)).
 228 When we let the number of demes go to infinity ($N_D \rightarrow \infty$) and the intensity of
 229 mutation be vanishingly small ($\mu \rightarrow 0$), we recover the classical formulas for re-
 230 latedness as limit cases (eq. (A45) and eq. (A51)).

231 The effects of emigration m and mutation intensity μ on relatedness are rep-
 232 resented in figure 1. For $0 < m < 1 - 1/N_D$, within-deme relatedness is positive,
 233 and it decreases with m and with μ (the mutation bias v has no effect). The effect
 234 of the mutation intensity μ on relatedness is strongest at low emigration prob-
 235 abilities m . As m increases, the relatedness values for different mutation inten-
 236 sities get closer, until they all hit zero for $m = 1 - 1/N_D$ (which is the emigration
 237 probability such that an offspring is equally likely to land in its parent's deme
 238 or in any other deme, *i.e.*, such that there is no proper population subdivision
 239 anymore).

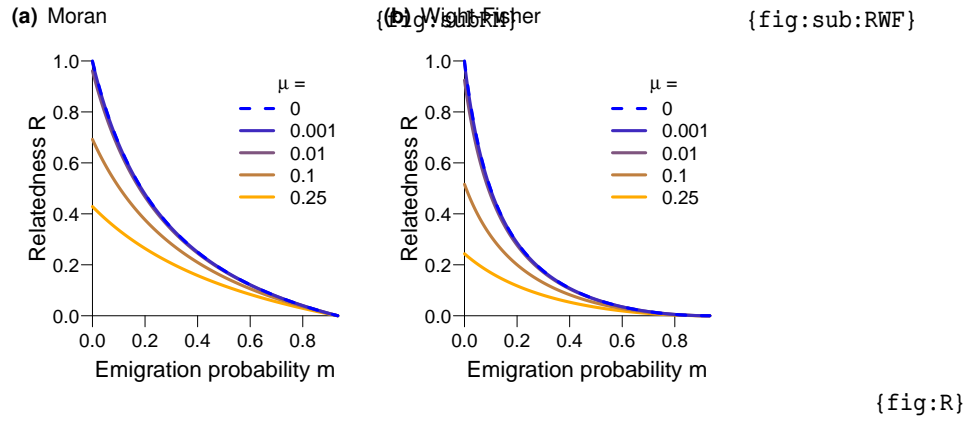

Figure 1: Within-deme relatedness of pairs of individuals R , as a function of the emigration probability m , for different values of the mutation probability μ (from 0 [blue] to 0.25 [orange]), and for the two types of life-cycles ((a): Moran, (b): Wright-Fisher). Other parameters: $n = 4$ individuals per deme, $N_D = 15$ demes.

240 Primary and secondary effects

241 We now turn to the \mathcal{B} and $-\mathcal{C}$ terms of eq. (5), which also depend on the cho-
 242 sen life-cycle. We further decompose these terms into primary (subscript P) and
 243 secondary (subscript S) effects (West & Gardner, 2010):

$$\begin{aligned}
 \mathcal{B} &= \mathcal{B}_P + \mathcal{B}_S, \\
 -\mathcal{C} &= \underbrace{-\mathcal{C}_P}_{\text{Primary effect}} + \underbrace{-\mathcal{C}_S}_{\text{Secondary effect}}.
 \end{aligned}
 \tag{6}$$

244 Primary effects correspond to unmediated consequences of interactions (they
 245 are included in $\frac{\partial W}{\partial f_i}$). Secondary effects correspond to consequences of interac-
 246 tions mediated by other individuals, including competition.

247 Primary effects

248 Primary effects are the same for all the life-cycles that we consider:

$$\mathcal{B}_P^{\text{BD}} = \mathcal{B}_P^{\text{DB}} = \mathcal{B}_P^{\text{WF}} = (1 - \mu)b, \quad (7a)$$

$$-\mathcal{C}_P^{\text{BD}} = -\mathcal{C}_P^{\text{DB}} = -\mathcal{C}_P^{\text{WF}} = (1 - \mu)(-c), \quad (7b)$$

249 and they do not depend on the emigration probability m (see Appendix B.2 for
250 details of the calculations).

251 As we have seen above, the relatedness terms R^{M} and R^{WF} decrease with m
252 (keeping $m < 1 - 1/N_D$; see figure 1). Consequently, if we ignored secondary
253 effects, we would conclude that the expected frequency of altruists in the popu-
254 lation $\mathbb{E}[\bar{X}]$ decreases as the emigration probability m increases. However, sec-
255 ondary effects play a role as well.

256 Secondary effects

257 Secondary effects take competition into account, that is, how the change in the
258 fecundity of an individual affects the fitness of another one. As shown already
259 in models with nearly perfect strategy transmission (Grafen & Archetti, 2008),
260 competition terms depend on the chosen life-cycle, because life-cycle details
261 affect the distance at which competitive effects are felt. Given the way the model
262 is formulated, we have $-\mathcal{C} = \mathcal{B}/(n - 1)$ for the life-cycles that we consider (see
263 Appendix B.2 for details of the calculations).

264 Under the Moran Birth-Death life-cycle, both the probability of reproducing
265 and the probability of dying depend on the composition of the population. We
266 obtain the following secondary effects:

{eq:secondary}

$$-\mathcal{C}_S^{\text{BD}} = \frac{\mathcal{B}_S^{\text{BD}}}{n - 1} = -(b - c) \left(-\frac{\mu}{N} + \frac{1 - m}{n} \right). \quad (8a) \quad \{\text{eq:BDsec}\}$$

267 The competitive effects are the same for the Moran Death-Birth and Wright-

268 Fisher life-cycles. In both cases, the probabilities of dying are constant, so we
 269 can factor $(1 - \mu)$ in the equations:

$$-C_S^{\text{DB}} = \frac{\mathcal{B}_S^{\text{DB}}}{n-1} = -C_S^{\text{WF}} = \frac{\mathcal{B}_S^{\text{WF}}}{n-1} = -(b-c)(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right). \quad (8b) \quad \{\text{eq:DBsec}\}$$

270 These secondary effects (eq. (8a) and eq. (8b)) remain negative for the range
 271 of emigration values that we consider ($0 < m < 1 - 1/N_D$), and increase with m . In
 272 other words, the intensity of competition decreases as emigration m increases.

273 While the value of these secondary effects increases with emigration m , re-
 274 latedness R , by which they are eventually multiplied in eq. (5), decreases with
 275 m . We therefore cannot determine the overall effect of emigration m on the ex-
 276 pected frequency of altruists in the population by inspecting the different terms
 277 of eq. (5) in isolation. For each life-cycle, we need to consider the entire equa-
 278 tions to know the overall effect of the emigration probability m on the expected
 279 frequency of altruists $\mathbb{E}[\bar{X}]$ and on how it is affected by the (in)fidelity of parent-
 280 offspring transmission μ .

281 **Changes of the expected frequency of altruists with the emigration prob-** 282 **ability m**

283 The rather lengthy formulas that we obtain are relegated to the Appendix and
 284 supplementary Mathematica file, and we concentrate here on the results.

285 **Moran Birth-Death**

286 For the Moran Birth-Death life-cycle, we find that the expected frequency of al-
 287 truists $\mathbb{E}[\bar{X}]$ is a monotonic function of the emigration probability m . The direc-
 288 tion of the change depends on the value of the mutation probability μ compared
 289 to a threshold value μ_c^{BD} . When $\mu < \mu_c^{\text{BD}}$, $\mathbb{E}[\bar{X}]$ decreases with m , while when

290 $\mu > \mu_c^{\text{BD}}$, $\mathbb{E}[\bar{X}]$ increases with m . The critical value μ_c^{BD} is given by

$$\mu_c^{\text{BD}} = 1 - \frac{b - c + \sqrt{(b - c)(4bN^2 + b - c)}}{2bN} \quad (9) \quad \{\text{eq:mucBD}\}$$

291 (recall that N is the total size of the population, $N = nN_D$.) This result is illus-
 292 trated in figure 2(b); with the parameters of the figure, $\mu_c^{\text{BD}} \approx 0.026$. The thresh-
 293 old value increases with both deme size n and number of demes N_D , up to a
 294 maximum value $1 - \sqrt{1 - c/b}$ (equal to 0.034 with our parameters.)

295 With this life-cycle however, the expected frequency of altruists $\mathbb{E}[\bar{X}]$ remains
 296 lower than v , its value in the absence of selection (*i.e.*, when $\delta = 0$).

297 **Moran Death-Birth**

298 The relationship between $\mathbb{E}[\bar{X}]$ and m is a bit more complicated for the Moran
 299 Death-Birth life-cycle. For simplicity, we concentrate on what happens starting
 300 from low emigration probabilities (*i.e.*, on the sign of the slope of $\mathbb{E}[\bar{X}]$ as a func-
 301 tion of m when $m \rightarrow 0$). If the benefits b provided by altruists are relatively low
 302 ($b < c(n + 1)$), $\mathbb{E}[\bar{X}]$ initially increases with m provided the mutation probability
 303 μ is greater than a threshold value μ_c^{DB} given in eq. (10) below; otherwise, when
 304 the benefits are high enough, $\mathbb{E}[\bar{X}]$ initially increases with m for any value of μ .
 305 Combining these results, we write

$$\mu_c^{\text{DB}} = \begin{cases} \frac{(n+1)c - b}{(2n-1)b - (n-1)c} & \text{if } b < c(n+1), \\ 0 & \text{otherwise.} \end{cases} \quad (10) \quad \{\text{eq:mucDB}\}$$

306 When $b < c(n + 1)$, the mutation threshold does not depend on the number of
 307 demes N_D , but increases with deme size n . In figure 2(a), the parameters are
 308 such that $\mu_c^{\text{DB}} = 0$.

309 When $\mu > \mu_c^{\text{DB}}$, the expected frequency of altruists $\mathbb{E}[\bar{X}]$ reaches a maximum
 310 at an emigration probability m_c^{DB} (whose complicated equation is given in the

311 supplementary Mathematica file), as can be seen in figure 2(a). When the muta-
 312 tion probability gets close to 0 ($\mu \rightarrow 0$), m_c^{DB} also gets close to 0.

313 With the Death-Birth life-cycle, the expected frequency of altruists is higher
 314 than its neutral value v for intermediate values of the emigration probability m
 315 (unless $\mu \rightarrow 0$, in which case the lower bound tends to 0).

316 **Wright-Fisher**

317 Under a Wright-Fisher updating, the expected frequency of altruists in the pop-
 318 ulation reaches an extremum at the highest admissible emigration value $m =$
 319 $1 - \frac{1}{N_D}$. This extremum is a maximum when the mutation probability is higher
 320 than a threshold value μ_c^{WF} given by

$$\mu_c^{\text{WF}} = 1 - \sqrt{1 - \frac{c}{b}}, \quad (11)$$

321 and it is a minimum otherwise. With the parameters of figure 2(c), $\mu_c^{\text{WF}} = 0.034$.

322 With the Wright-Fisher life-cycle however, the expected frequency of altruists
 323 remains below its value in the absence of selection, v .

324 **Relaxing key assumptions**

325 To derive our analytical results, we had to make a number of simplifying as-
 326 sumptions, such as the fact that selection is weak ($\delta \ll 1$), and the fact that
 327 the structure of the population is regular (all demes have the same size n). We
 328 checked with numerical simulations the robustness of our results when these
 329 key assumptions are relaxed.

330 **Strong selection** When selection is strong, the patterns that we identified not
 331 only still hold but are even more marked, as shown on figure A1.

Figure 2: Expected proportion of altruists under weak selection, as a function of the emigration probability m , for different mutation values ($\mu = 0.001$ (blue, dots), 0.01 (purple, squares), 0.1 (brown, diamonds), 0.25 (orange, triangles); the dashed blue lines correspond to $\mu = 0$) and different life-cycles ((a) Moran Death-Birth, (b) Moran Birth Death, (c) Wright-Fisher). The curves are the analytical results, the points are the output of numerical simulations. Parameters: $\delta = 0.005$, $v = 0.45$, $b = 15$, $c = 1$, $n = 4$ individuals per deme, $N_D = 15$ demes.

332 **Heterogeneity in deme sizes** To relax the assumption of equal deme sizes, we
 333 randomly drew deme sizes at the beginning of simulations, with sizes ranging
 334 from 2 to 6 individuals and on average $\bar{n} = 4$ individuals per deme as previously.
 335 As shown in figure A2, the patterns initially obtained with a homogeneous pop-
 336 ulation structure are robust when the structure is heterogeneous.

337 **No self-replacement** For the Moran model, it may seem odd that an offspring
 338 can replace its own parent (which can occur since $d_{ii} \neq 0$). Figure A3, plotted
 339 with dispersal probabilities preventing immediate replacement of one's own par-
 340 ent (for all sites i , $d_{ii} = d_{\text{self}} = 0$; $d_{\text{in}} = (1 - m)/(n - 1)$ for two different sites in the
 341 same deme, d_{out} remaining unchanged), confirms that this does affect our con-
 342 clusions.

343 **Infinite number of demes** Our results are obtained in a population of finite
 344 size (the figures are drawn with $N_D = 15$ demes), but still hold when the size of
 345 the population is larger. Figure 3(b) shows the range of emigration and mutation
 346 values such that altruism is favored, plotted also for $N_D \rightarrow \infty$.

347 **Same graphs for dispersal and social interactions** Compared to graphs classi-
 348 cally used in evolutionary graph theory (*e.g.*, regular random graphs, grids), the
 349 island model is particular because the interaction graph and the dispersal graph
 350 are different: interactions take place only within demes ($e_{\text{out}} = 0$), while offspring
 351 can disperse out of their natal deme ($d_{\text{out}} > 0$). One may wonder whether our re-
 352 sult depends on this difference between the two graphs. Figure A4 shows that the
 353 result still holds when the dispersal and interaction graphs are the same. In this
 354 figure indeed, we let a proportion m (equal to the dispersal probability) of inter-
 355 actions occur outside of the deme where the individuals live, and set d_{self} , the
 356 probability of self replacement, equal to 0, so that the dispersal and interactions
 357 graphs are the same. Our conclusions remain unchanged.

358 Discussion

359 The expected frequency of altruists in a subdivided population can in- 360 crease with the probability of emigration

361 Assuming that the transmission of a social strategy (being an altruist or a defec-
362 tor) from a parent to its offspring could be imperfect, we found that the expected
363 frequency of altruists maintained in a population could increase with the prob-
364 ability m of emigration out of the parental deme, a parameter tuning population
365 viscosity. This result can seem surprising, because it contradicts the conclusions
366 obtained under the assumption of nearly perfect strategy transmission (*i.e.*, in
367 the case of genetic transmission, when mutation is very weak or absent). Under
368 nearly perfect strategy transmission indeed, increased population viscosity (*i.e.*,
369 decreased emigration probability) is either neutral (Taylor, 1992a, and dashed
370 lines in figures 2(b)–(c)) or favorable (Taylor et al., 2007a, and dashed lines in
371 figure 2(a)) to the evolution of altruistic behavior.

372 Quantitative vs. qualitative measures

373 Often, evolutionary success is measured qualitatively, by comparing a quantity
374 (an expected frequency, or, in models with no mutation, a probability of fixa-
375 tion) to the value it would have in the absence of selection. In our model, this
376 amounts to saying that altruism is favored whenever $\mathbb{E}[\bar{X}] > \nu$ (ν is plotted as a
377 horizontal dashed line in figure 2). Some of our conclusions change if we use this
378 qualitative measure of evolutionary success: Under the Moran Birth-Death and
379 Wright-Fisher life-cycles, population viscosity does not promote the evolution of
380 altruism – actually, these two life-cycles cannot ever promote altruistic behavior
381 for any regular population structure (Taylor et al., 2011), whichever the probab-
382 ility of mutation (Débarre, 2017). However, under a Moran Death-Birth life-cycle
383 (figure 2(a)), altruism can be favored only at intermediate emigration probab-

ities. Starting for initially low values of m , increasing the emigration probability can still favor the evolution of altruism under this qualitative criterion (see figure 3(b).)

Interpreting the effect of m on $\mathbb{E}[\bar{X}]$

To better understand the role played by the mutation intensity μ , we focus on the qualitative condition for the evolution of altruism ($\mathbb{E}[\bar{X}] > \nu$); and on the Death-Birth life-cycle, since this qualitative condition is not satisfied in the two other life-cycles. Having made sure that $\mathcal{B}^{\text{DB}} > 0$ (as shown in the supplementary Mathematical file), the qualitative condition for altruism to be favored is given by

$$\mathbb{E}[\bar{X}] > \nu \Leftrightarrow R^{\text{M}} > \frac{\mathcal{C}^{\text{DB}}}{\mathcal{B}^{\text{DB}}}. \quad (12) \quad \{\text{eq:BCcond}\}$$

With the Death-Birth life-cycle, the $\mathcal{C}^{\text{DB}}/\mathcal{B}^{\text{DB}}$ ratio does not change with the mutation probability μ (the $(1 - \mu)$ factors simplified out), but the ratio decreases with the emigration probability m (with $0 < m < 1 - 1/N_D$; see the thick black curve in figure 3(a)). This decrease of the $\mathcal{C}^{\text{DB}}/\mathcal{B}^{\text{DB}}$ ratio is due to secondary effects (competition) diminishing as emigration increases. Relatedness, on the other hand, decreases with both μ and m (see figure 3(a)). We need to explain the effect of the emigration probability m on condition (12) for different values of mutation intensity μ .

When the emigration probability m is high, relatedness gets closer to zero for all values of mutation intensity μ , while the $\mathcal{C}^{\text{DB}}/\mathcal{B}^{\text{DB}}$ remains positive; condition (12) is not satisfied. On the other hand, when the emigration probability m is vanishingly small, $\lim_{m \rightarrow 0} R^{\text{M}} \leq \lim_{m \rightarrow 0} \frac{\mathcal{C}^{\text{DB}}}{\mathcal{B}^{\text{DB}}}$, the two only being equal when $\mu = 0$. Hence, condition (12) is satisfied for vanishingly low m only when strategy transmission is perfect. Finally, as m increases to intermediate values, the $\frac{\mathcal{C}^{\text{DB}}}{\mathcal{B}^{\text{DB}}}$ ratio decreases with a steeper slope than relatedness R , so that the curves can cross provided the mutation probability μ is not too high, *i.e.*, that R was not ini-

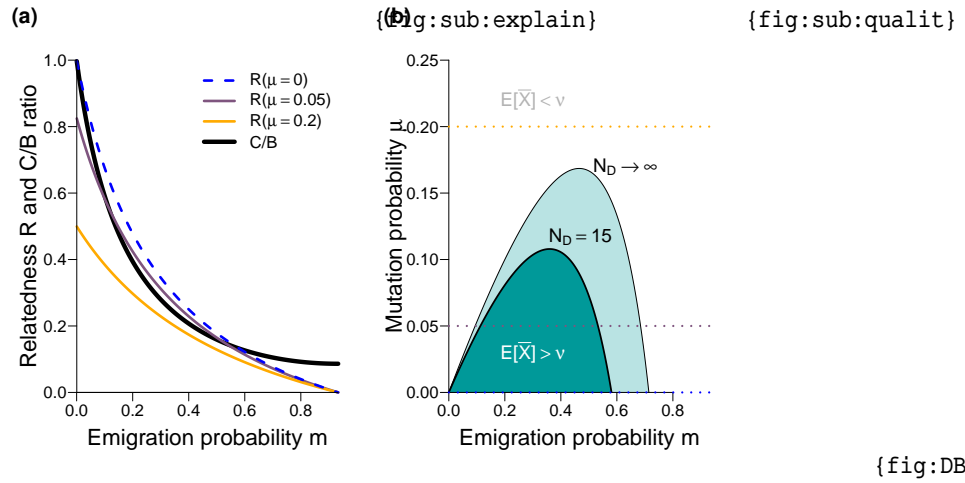

Figure 3: Understanding the effect of emigration m on whether altruism is favored in the Death-Birth life-cycle. (a) Comparison of the C/B ratio (thick black curve) and relatedness R (thin curves) for different values of the mutation probability μ (same color code as previously). (b) (m, μ) combinations for which $E[\bar{X}] > v$. The dotted horizontal lines correspond to the mutation values used in panel (a). Unless specified, all other parameters are the same as in figure 2.

tially too low already. Hence, for no too high mutation intensity, there is a range of emigration values m such that condition (12) is satisfied.

The result is due to secondary effects

The result, that frequency of altruists can increase with the emigration probability m , may seem counterintuitive. It is the case because verbal explanations for the evolution of altruism often rely on primary effects only. Relatedness R decreases with m , so it may be tempting to conclude that increases in the emigration probability m are necessarily detrimental to the evolution of altruism. However, secondary effects play an opposite role, as competition decreases with m , and the effect is strongest at low values of m (see the black curve on figure 3(a); in the absence of secondary effects, it would just be a horizontal line).

Secondary effects are less straightforward to understand than primary effects, and yet they play a crucial role for social evolution in spatially structured

populations. Competition among relatives is for instance the reason for Taylor (1992b)’s cancellation result. Similarly, the qualitative differences between the Moran Birth-Death and Moran Death-Birth life-cycles is explained by the different scales of competition that the two life-cycle produce (Grafen & Archetti, 2008; Débarre et al., 2014). Secondary effects are also behind the evolution of social behaviors such as spite (West & Gardner, 2010).

Other model

How small is small and how large is large?

Our results were derived under the assumption of weak selection, assuming that the phenotypic difference between altruists and defectors is small ($\delta \ll 1$). We considered any fidelity of transmission (any μ between 0 and 1) and population size. However, most models considering subdivided populations assume nearly perfect strategy transmission ($\mu \rightarrow 0$) and infinite population sizes (number of demes $N_D \rightarrow \infty$). The point is technical, but it is important to know that the order in which these limits are taken matters, *i.e.*, one needs to specify how small μ and δ are compared to the inverse size of the population $1/N$. This remark complements findings by Sample & Allen (2017), who highlighted the quantitative differences between different orders of weak selection and large population limits.

Imperfect transmission and Rebellious Children

Our model bears resemblance to the Rebellious Child Model by Frank (1997), who studied the evolution of a vertically transmitted cultural trait in an asexually reproducing population. In Frank’s model, however, relatedness r is treated as a fixed parameter (Frank, 1997, legend of Figure 7). Our model is mechanistic; relatedness r necessarily depends on the mutation probability μ , because probabilities of identity by descent do.

449 Mutation was also previously included in models investigating the maintenance of cooperative microorganisms in the presence of cheaters (Brockhurst
450 et al., 2007; Frank, 2010). In both of these models however, only loss-of-function
451 mutation was considered, which corresponds to setting the mutation bias at
452 $\nu = 0$ in our model. This means that the all-cheaters state is absorbing; no matter
453 how favored cooperators may otherwise be, in the long run, a finite population
454 will only consist of cheaters.

456 **Cultural transmission**

457 Strategy transmission does not have to be genetic: it can be cultural. In our
458 model, strategy transmission occurs upon reproduction, so this is a case of ver-
459 tical cultural transmission.

460 The model could nevertheless be interpreted as a representation of horizon-
461 tal transmission, if we described reproduction as an instance of an individual
462 convincing another one to update its strategy. The Moran Death-Birth model
463 can be interpreted as a modified imitation scheme (Boyd & Richerson, 2002; Oht-
464 suki et al., 2006) – with a specific function specifying who is imitated –, with mu-
465 tation (Kandori et al., 1993). First, we choose uniformly at random an individual
466 who may change its strategy; with probability μ the individual chooses a random
467 strategy (altruistic with probability ν), and with probability $1 - \mu$ it imitates an-
468 other individual. Who is imitated depends on the distance to the focal individual
469 (with probability m it is a random individual in another deme) and on the “fe-
470 cundities” of those individuals (as shown in table A2). With this interpretation of
471 the updating rule however, there is not reproduction nor death anymore.

472 It remains to be investigated how imperfect strategy transmission would af-
473 fect the effect of population viscosity on the evolution of altruism in a model im-
474 plementing both reproduction and horizontal cultural transmission (as in Lehmann
475 et al., 2008). Such a model could then contrast the effects of imperfect genetic

476 transmission and imperfect horizontal cultural transmission.

477 **Coevolution of dispersal and social behavior**

478 This work also raises the question of what would happen if dispersal (*e.g.*, the
479 emigration probability m) could evolve as well. Recent work on the topic has
480 shown that under some conditions disruptive selection could take place, lead-
481 ing to a polymorphism between sessile altruists and mobile defectors (Parvinen,
482 2013; Mullan et al., 2017). The assumptions of these studies however differ from
483 ours in important ways, in that they consider continuous traits and use an adap-
484 tive dynamics framework, where, notably, mutations are assumed to be very
485 rare. It remains to be investigated how non-rare and potentially large mutations
486 would affect their result.

| \mathcal{C} | Marginal effect of an individual's phenotype on its own fitness W |
| d_{ij} | Dispersal probability from site i to site j |
| D_i | Probability that the individual currently living at site i is dead at the end of the time step (r.v.) |
| e_{ij} | Interaction probability from site i to site j |
| f_i | Fecundity of the individual currently living at site i (r.v.) |
| n | Deme size |
| N_D | Number of demes |
| N | Total population size ($N = N_D n$) |
| m | Emigration probability |
| P_{ij} | (Long-term) Expected state of the pair of sites (i, j) |
| Q_{ij} | (Long-term) Probability of identity by descent of individuals at sites i and j |
| R | Pairwise within-deme relatedness (see eq. (5)) |
| W_i | Measure of fitness, counting offspring only when unmutated (see eq. (3)) |
| X_i | Indicator variable, equal to 1 if site i is occupied by an altruist, to 0 otherwise (r.v.) |
| \bar{X} | Frequency of altruists in the population (r.v.) |
| δ | Phenotypic distance between altruists and defectors; strength of selection |
| ϕ_i | Phenotype of the individual living at site i ; $\phi_i = \delta X_i$ (r.v.) |
| μ | Mutation probability |
| ν | Mutation bias: probability that mutant is altruist |
| P | Subscript corresponding to primary effects |
| S | Subscript corresponding to secondary effects |
| • | Subscript used to denote a focal individual |
| in | Subscript used when $i \neq j$ and the two sites are in the same deme |
| out | Subscript used when the two sites i and j are in different demes |
| self | Subscript used when $i = j$ |
| 0 | Sub- or superscript meaning that a quantity is evaluated at $\delta = 0$ |
| BD | Superscript corresponding to the Moran Birth-Death model |
| DB | Superscript corresponding to the Moran Death-Birth model |
| M | Superscript corresponding to a Moran model |
| WF | Superscript corresponding to the Wright-Fisher model |

{tab:symbols}

Table A1: List of symbols. "r.v." means *random variable*.

Appendix

A Mutation parameters

{sec:app:mutation}

In the main text, we first introduce effective mutation parameters: $\mu_{1 \rightarrow 0}$, the probability that an altruist has defector offspring, and $\mu_{0 \rightarrow 1}$, the probability that a defector has altruist offspring.

A.1 Expected frequency of altruists at the mutation-drift balance

{sec:app:defnu}

We assume that there is no selection acting ($\delta = 0$), but that there still are two types of individuals in the population.

Let Y be the type of a randomly chosen individual in the population, given a proportion y of altruists in the population. In expectation, we have

$$\mathbb{E}[Y] = y. \quad (\text{A1a})$$

Let Y' be the type of a randomly chosen individual at the next time step, given the frequency y at the previous time step. This randomly chosen individual is altruist if its parent was (y) and it did not mutate ($\mu_{1 \rightarrow 0}$), or if its parent was not altruist ($1 - y$), but the offspring mutated into one ($\mu_{0 \rightarrow 1}$). We obtain

$$\mathbb{E}[Y'] = y(1 - \mu_{1 \rightarrow 0}) + (1 - y)\mu_{0 \rightarrow 1}. \quad (\text{A1b})$$

The expected frequency of altruists, denoted by ν , is found by solving $\mathbb{E}[Y] = \mathbb{E}[Y']$. We obtain

$$\nu = \frac{\mu_{0 \rightarrow 1}}{\mu_{1 \rightarrow 0} + \mu_{0 \rightarrow 1}}. \quad (\text{A2}) \quad \{\text{eq:app:nuformula}\}$$

A.2 Parent-offspring correlation at the mutation drift balance

We can then compute the parent-offspring type correlation at the mutation-drift balance. First, let us compute parent-offspring covariance:

$$\begin{aligned} \text{Cov}[Y Y'] &= \mathbb{E}[Y Y'] - \mathbb{E}[Y'] \mathbb{E}[Y] \\ &= \nu(1 - \mu_{1 \rightarrow 0}) - (\nu(1 - \mu_{1 \rightarrow 0}) + (1 - \nu)\mu_{0 \rightarrow 1})\nu \\ &= \nu(1 - \nu)(1 - \mu_{1 \rightarrow 0} - \mu_{0 \rightarrow 1}). \end{aligned} \quad (\text{A3}) \quad \{\text{eq:app:Cov}\}$$

Then, the standard deviations are given by

$$\begin{aligned} \sigma_Y &= \sqrt{\mathbb{E}[Y^2] - \mathbb{E}[Y]^2} = \sqrt{\mathbb{E}[Y] - \mathbb{E}[Y]^2} \\ &= \sqrt{\nu(1 - \nu)}, \end{aligned} \quad (\text{A4}) \quad \{\text{eq:app:SD1}\}$$

and

$$\begin{aligned} \sigma_{Y'} &= \sqrt{\mathbb{E}[Y'^2] - \mathbb{E}[Y']^2} = \sqrt{\mathbb{E}[Y'] - \mathbb{E}[Y']^2} \\ &= \sqrt{\nu(1 - \nu)(1 - \mu_{1 \rightarrow 0} - \mu_{0 \rightarrow 1}) - (\nu(1 - \nu)(1 - \mu_{1 \rightarrow 0} - \mu_{0 \rightarrow 1}))^2}. \end{aligned} \quad (\text{A5}) \quad \{\text{eq:app:SD2}\}$$

617 Finally, the parent-offspring correlation is given by

$$\text{Corr}[Y Y'] = \frac{\text{Cov}[Y Y']}{\sigma_Y \sigma_{Y'}};$$

618 using the formulas eq. (A3)–(A5), and replacing ν by its value (mutation-drift
619 equilibrium, eq. (A2)), we obtain

$$\text{Corr}[Y Y'] = 1 - (\mu_{1 \rightarrow 0} + \mu_{0 \rightarrow 1}) = 1 - \mu. \quad (\text{A6})$$

620 **A.3 Redefining the mutation scheme**

{sec:app:mutnew}

621 With the new mutation parameters μ and ν , we can describe the mutation scheme
622 differently.

623 If we denote by X_i the type of a given parent, then the expected type of one
624 of its offspring is

$$\mathbb{E}[X'_i | X_i] = X_i(1 - \mu_{1 \rightarrow 0}) + (1 - X_i)\mu_{0 \rightarrow 1}. \quad (\text{A7a}) \quad \{\text{eq:app:expoff}\}$$

625 Replacing $\mu_{1 \rightarrow 0}$ and $\mu_{0 \rightarrow 1}$ by equivalent combinations of μ and ν , *i.e.*,

$$\mu_{1 \rightarrow 0} = \mu(1 - \nu) \text{ and } \mu_{0 \rightarrow 1} = \mu\nu, \quad (\text{A7b})$$

626 then eq. (A7a) becomes

$$\mathbb{E}[X'_i | X_i] = X_i(1 - \mu) + \mu\nu. \quad (\text{A7c}) \quad \{\text{eq:app:expoff2}\}$$

627 We can redefine the mutation scheme and interpret eq. (A7c) as follows. Parents
628 transmit their strategy to their offspring with probability $1 - \mu$; with probability
629 μ , offspring do not inherit their strategy from their parent but instead get one
630 randomly: with probability ν , they become altruists, with probability $1 - \nu$ they
631 become defectors. With this alternative description, we can call “mutants” indi-
632 viduals who have the same type as their parent.

B Expected frequency of altruists

{sec:app:EX}

B.1 For a generic life-cycle

{sec:app:generic}

We want to compute the expected proportion of altruists in the population. We represent the state of the population at a given time t using indicator variables $X_i(t)$, $1 \leq i \leq N$, equal to 1 if the individual living at site i at time t is an altruist, and equal to 0 if it is a defector; these indicator variables are gathered in a N -long vector $\mathbf{X}(t)$. The set of all possible population states is $\Omega = \{0, 1\}^N$. The proportion of altruists in the population is written $\bar{X}(t) = \sum_{i=1}^N X_i(t)$. We denote by $B_{ji}(X(t), \delta)$, written B_{ji} for simplicity, the probability that the individual at site j at time $t+1$ is the newly established offspring of the individual living at site i at time t . The expected number of successful offspring produced by the individual living at site i at time t is given by $B_i = \sum_{j=1}^N B_{ji}$. We denote by $D_i(X(t), \delta)$ (D_i for simplicity) the probability that the individual living at site i at time t has been replaced (*i.e.*, died) at time $t+1$. These quantities depend on the chosen life-cycle and on the state of the population; they are given in table A2 for each of the life-cycles that we consider.

| Life-cycle | B_{ji} | D_i |
|-------------------|--|--|
| Moran Birth-Death | $d_{ij} \frac{f_i}{\sum_{k=1}^N f_k}$ | $\frac{\sum_{j=1}^N d_{ji} f_j}{\sum_{k=1}^N f_k}$ |
| Moran Death-Birth | $\frac{1}{N} \frac{d_{ij} f_i}{\sum_{k=1}^N d_{kj} f_k}$ | $\frac{1}{N}$ |
| Wright-Fisher | $\frac{d_{ij} f_i}{\sum_{k=1}^N d_{kj} f_k}$ | 1 |

{tab:BD}

Table A2: Formulas of B_{ji} and D_i for each of the life-cycles that we consider; f_i (shorthand notation for $f_i(X, \delta)$) is the fecundity of the individual living at site i , and d_{ji} is a dispersal probability, given in eq. (2).

Since a dead individual is immediately replaced by one new individual (*i.e.*, population size remains constant and equal to N),

$$D_i = \sum_{j=1}^N B_{ij} \quad (\text{A8a}) \quad \{\text{eq:DBequiv}\}$$

holds for all sites i and all life-cycles.

The structure of the population is also such that in the absence of selection ($\delta = 0$, so that $f_i = 1$ for all sites $1 \leq i \leq N$), all individuals have the same probability of dying and the same probability of having successful offspring (*i.e.*, of

655 having offspring that become adults at the next time step), so that

$$D_i^0 = \sum_{j=1}^N B_{ji}^0 = B_i^0 =: B^*, \quad (\text{A8b}) \quad \{\text{eq:DBRV}\}$$

656 where the ⁰ subscript means that the quantities are evaluated for $\delta = 0$. This
 657 also implies that B_{ij}^0 and D_i^0 do not depend on the state \mathbf{X} of the population. For
 658 the Moran life-cycles, $B^* = 1/N$, while for the Wright-Fisher life-cycle, $B^* = 1$.
 659 (The difference between eq. (A8b) and eq. (A8a) is that we are now considering
 660 offspring produced by i landing on j).

661 Given that the population is in state $\mathbf{X}(t)$ at time t , the expected frequency of
 662 altruists at time $t + 1$ is given by

$$\mathbb{E}[\bar{X}(t+1)|\mathbf{X}(t)] = \frac{1}{N} \sum_{i=1}^N [B_i(1-\mu)X_i + (1-D_i)X_i + B_i\mu\nu]. \quad (\text{A9a}) \quad \{\text{eq:conditionalchange}\}$$

663 The first term within the brackets corresponds to births of unmutated offspring
 664 from parents who are altruists (X_i). The second term corresponds to the survival
 665 of altruists. The third term corresponds to the births of mutants who became
 666 altruists (which occurs with probability ν), whichever the type of the parent.

667 Given that there is no absorbing population state (a lost strategy can always
 668 be recreated by mutation), there is a stationary distribution of population states;
 669 the expected frequency of altruists does not change anymore for large times t
 670 (realized frequencies of course keep changing). We denote by $\xi(\mathbf{X}, \delta, \mu)$ the prob-
 671 ability that the population is in state \mathbf{X} , given the strength of selection δ and the
 672 mutation probability μ . Taking the expectation of eq. (A9a) ($\mathbb{E}[\bar{X}] = \sum_{\mathbf{X} \in \Omega} \bar{X} \xi(\mathbf{X}, \delta, \mu)$),
 673 we obtain, after reorganizing:

$$0 = \frac{1}{N} \sum_{\mathbf{X} \in \Omega} \left[\sum_{i=1}^N (B_i(1-\mu)X_i - D_iX_i) + \sum_{i=1}^N B_i\mu\nu \right] \xi(\mathbf{X}, \delta, \mu). \quad (\text{A10}) \quad \{\text{eq:statdist}\}$$

674 Now, we use the assumption of weak selection ($\delta \ll 1$) and consider the first-
 675 order expansion of eq. (A10) for δ close to 0.

$$\begin{aligned} 0 = & \frac{1}{N} \sum_{\mathbf{X} \in \Omega} \left[\sum_{i=1}^N (B_i^0(1-\mu)X_i - D_i^0X_i) + \sum_{i=1}^N B_i^0\mu\nu \right] \xi(\mathbf{X}, 0, \mu) \\ & + \frac{1}{N} \sum_{\mathbf{X} \in \Omega} \left[\sum_{i=1}^N \left(\frac{\partial B_i(1-\mu)}{\partial \delta} X_i - \frac{\partial D_i}{\partial \delta} X_i \right) + \sum_{i=1}^N \frac{\partial B_i}{\partial \delta} \mu\nu \right] \xi(\mathbf{X}, 0, \mu) \\ & + \frac{1}{N} \sum_{\mathbf{X} \in \Omega} \left[\sum_{i=1}^N (B_i^0(1-\mu)X_i - D_i^0X_i) + \sum_{i=1}^N B_i^0\mu\nu \right] \frac{\partial \xi(\mathbf{X}, \delta, \mu)}{\partial \delta}, \end{aligned} \quad (\text{A11}) \quad \{\text{eq:app:TaylorDetail}\}$$

676 where all the derivatives are evaluated for $\delta = 0$. The first line of eq. (A11) is equal
 677 to zero, because $B_i^0 = D_i^0 = B^*$ (eq. (A8b)), and because in the absence of selec-
 678 tion ($\delta = 0$), the expected state of every site i is $\mathbb{E}_0[X_i] = \sum_{\mathbf{X} \in \Omega} X_i \xi(\mathbf{X}, 0, \mu) = \nu$
 679 (by definition of ν , see Appendix A.1). The second terms of the second and third

lines are both zero, because for all the life-cycles that we consider, the total number of births in the population during one time step ($\sum_{i=1}^N B_i$) does not depend on population phenotypic composition (it is exactly 1 death for the Moran life-cycles, and exactly N for the Wright-Fisher life-cycle). Eq. (A11) then becomes

$$0 = \frac{\delta}{N} \sum_{i=1}^N \left[\sum_{X \in \Omega} \left(\frac{\partial B_i}{\partial \delta} (1 - \mu) - \frac{\partial D_i}{\partial \delta} \right) X_i \xi(\mathbf{X}, 0, \mu) - \sum_{X \in \Omega} \mu B^* X_i \frac{\partial \xi}{\partial \delta} \right] + O(\delta^2), \quad (\text{A12}) \quad \{\text{eq:weaksel0}\}$$

where the derivatives are evaluated at $\delta = 0$. For conciseness, we define

$$W_i = (1 - \mu) B_i + (1 - D_i), \quad (\text{A13}) \quad \{\text{eq:app:defW}\}$$

a measure of fitness counting offspring only when they are unmutated (in the sense of the alternate mutation scheme described in Appendix A.3). With this, using the expectation notation, and denoting by $\mathbb{E}_0[\cdot]$ expectations under $\delta = 0$, we can rewrite and reorganize eq. (A12) as

$$\delta \mu B^* \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} = \frac{\delta}{N} \sum_{i=1}^N \mathbb{E}_0 \left[\frac{\partial W_i}{\partial \delta} X_i \right] + O(\delta^2). \quad (\text{A14}) \quad \{\text{eq:weaksel0reorg}\}$$

Now, we use a first time the law of total probabilities, taking individual phenotypes ϕ_k are intermediate variables:

$$\begin{aligned} \frac{\partial W_i}{\partial \delta} &= \sum_{k=1}^N \frac{\partial W_i}{\partial \phi_k} \frac{\partial \phi_k}{\partial \delta} \\ &= \sum_{k=1}^N \frac{\partial W_i}{\partial \phi_k} X_k, \end{aligned} \quad (\text{A15}) \quad \{\text{eq:totalproba1}\}$$

by definition of ϕ_k ($\phi_k = \delta X_k$), and where the derivatives are evaluated for all $\phi_i = 0$, $1 \leq i \leq N$. Introducing the notation $P_{ij} = \mathbb{E}_0[X_i X_j]$ (expected state of a pair of sites), eq. (A14) becomes

$$\delta \mu B^* \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} = \frac{\delta}{N} \sum_{i=1}^N \sum_{k=1}^N \frac{\partial W_i}{\partial \phi_k} P_{ik} + O(\delta^2). \quad (\text{A16}) \quad \{\text{eq:weaksel1}\}$$

So far, we have not used the specificities of the population structure that we consider. Once we have fixed a focal individual i , in expectation there are only three types of individuals: the focal itself (denoted by “•”), $n - 1$ other individuals in the focal’s deme (denoted by “in”), and $N - n$ individuals in other demes (denoted by “out”). We note that given that the size of the population is fixed ($\sum_{i=1}^N (B_i - D_i) = 0$), and given that the total number of births does not depend on population composition in the life-cycles that we consider,

$$\sum_{i=1}^N \frac{\partial W_i}{\partial \delta} = 0,$$

701 which we can rewrite as (Rousset & Billiard, 2000, p.817–818)

$$\frac{\partial W_i}{\partial \phi_i} + (n-1) \frac{\partial W_i}{\partial \phi_{\text{in}}} + (N-n) \frac{\partial W_i}{\partial \phi_{\text{out}}} = 0. \quad (\text{A17}) \quad \{\text{eq:derivsumW}\}$$

702 With this, eq. (A16) becomes

$$\delta \mu B^* \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} = \frac{\delta}{N} \sum_{i=1}^N \left(\frac{\partial W_i}{\partial \phi_i} + (n-1) \frac{\partial W_i}{\partial \phi_{\text{in}}} \frac{P_{\text{in}} - P_{\text{out}}}{P_{ii} - P_{\text{out}}} \right) (P_{ii} - P_{\text{out}}) + O(\delta^2). \quad (\text{A18}) \quad \{\text{eq:weaksel1CBRP}\}$$

703 We can also replace the P terms by

$$\begin{aligned} P_{ij} &= Q_{ij} \nu + (1 - Q_{ij}) \nu^2 \\ &= \nu^2 + \nu(1 - \nu) Q_{ij}. \end{aligned} \quad (\text{A19}) \quad \{\text{eq:QP}\}$$

704 In Appendix C.1, using recursions on P_{ij} , we will see that Q_{ij} can be interpreted
 705 as a probability of identity by descent, *i.e.*, the probability that the individuals at
 706 sites i and j have a common ancestor and that no mutation (using the alterna-
 707 tive mutation scheme described in Appendix A.3) has occurred on either lineage
 708 since the ancestor. Eq. (A18) becomes

$$\delta \mu B^* \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} = \frac{\delta}{N} \sum_{i=1}^N \left(\underbrace{\frac{\partial W_i}{\partial \phi_i}}_{-C} + (n-1) \underbrace{\frac{\partial W_i}{\partial \phi_{\text{in}}}}_{B} \underbrace{\frac{Q_{\text{in}} - Q_{\text{out}}}{1 - Q_{\text{out}}}}_R \right) (1 - Q_{\text{out}}) \nu (1 - \nu) + O(\delta^2). \quad (\text{A20}) \quad \{\text{eq:weaksel1CBR}\}$$

709 We can further decompose the derivatives, now using the fecundities f_ℓ as
 710 intermediate variables, *i.e.*,

$$\frac{\partial W_i}{\partial \phi_k} = \sum_{\ell=1}^N \frac{\partial W_i}{\partial f_\ell} \frac{\partial f_\ell}{\partial \phi_k}. \quad (\text{A21})$$

711 The term $\frac{\partial f_\ell}{\partial \phi_k}$ is the marginal effect of a change in the phenotype of the in-
 712 dividual living at site k on the fecundity of the individual living at site ℓ . By as-
 713 sumption, social interactions take place within demes only, so whenever ℓ and k
 714 are in different demes, we have $\frac{\partial f_\ell}{\partial \phi_k} = \frac{\partial f_\ell}{\partial \phi_{\text{out}}} = 0$. We then need to characterize the
 715 effect of one's own phenotype ($k = \ell$) and of another deme-mate's phenotype (k
 716 and ℓ different sites in the same deme) on fecundity, and define {\text{eq:derivf}}

$$\left. \frac{\partial f_\ell}{\partial \phi_\ell} \right|_{\delta=0} = -c, \quad (\text{A22a})$$

$$\left. \frac{\partial f_\ell}{\partial \phi_{\text{in}}} \right|_{\delta=0} = \frac{b}{n-1}. \quad (\text{A22b})$$

717 Eq. (A20) then becomes (using notation \bullet to refer to the focal individual itself,

718 and where $W = W_i$, since the derivatives are the same for all i):

$$\begin{aligned} \delta \mu B^* \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} &= \delta \nu (1 - \nu) (1 - Q_{\text{out}}) \times \\ &\quad \left(\underbrace{\left(\frac{\partial W}{\partial f} (-c) + \frac{\partial W}{\partial f_{\text{in}}} b \right)}_{-C} + \underbrace{\left(\frac{\partial W}{\partial f} b + (n-1) \frac{\partial W}{\partial f_{\text{in}}} (-c) + (n-2) \frac{\partial W}{\partial f_{\text{in}}} b \right)}_B \underbrace{\frac{Q_{\text{in}} - Q_{\text{out}}}{1 - Q_{\text{out}}}}_R \right) + O(\delta^2). \end{aligned} \quad (\text{A23}) \quad \{\text{eq:weaksel2}\}$$

719 (As previously, all derivatives are evaluated at $\delta = 0$.)

720 Finally, we obtain a first-order approximation of the expected frequency of
721 altruists in the population with

$$\mathbb{E}[\bar{X}] = \nu + \delta \left. \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} \right|_{\delta=0} + O(\delta^2), \quad (\text{A24}) \quad \{\text{eq:app:EXgeneric}\}$$

722 where $\nu = \mathbb{E}_0[\bar{X}]$ (expected frequency in the absence of selection), and where
723 $\left. \frac{\partial \mathbb{E}[\bar{X}]}{\partial \delta} \right|_{\delta=0}$ is obtained from eq. (A23). We then need to replace the B_i and D_i
724 terms by their formulas for each life-cycle; they are given in table A2.

725 B.2 Derivatives for the specific life-cycles

{sec:app:dW}

726 We use the formulas presented in table A2 and the definition of $W = W_i$ given
727 in eq. (A13) for each life-cycle. In eq. (A26), eq. (A28) and eq. (A30), the first
728 lines within parentheses correspond to primary effects, and the second line to
729 secondary effects.

730 **Moran Birth-Death** Under this life-cycle, we obtain

{eq:dWBD}

$$\left. \frac{\partial W^{\text{BD}}}{\partial f} \right|_{\delta=0} = (1 - \mu) \left(\frac{1}{N} - \frac{1}{N^2} \right) - \left(\frac{1 - m}{nN} - \frac{1}{N^2} \right) = \frac{1 - \mu}{N} + \frac{\mu}{N^2} - \frac{1 - m}{nN}, \quad (\text{A25a})$$

$$\left. \frac{\partial W^{\text{BD}}}{\partial f_{\text{in}}} \right|_{\delta=0} = (1 - \mu) \left(-\frac{1}{N^2} \right) - \left(\frac{1 - m}{nN} - \frac{1}{N^2} \right) = \frac{\mu}{N^2} - \frac{1 - m}{nN}. \quad (\text{A25b})$$

731 With these derivatives, eq. (5) becomes

$$\begin{aligned} \mathbb{E}[\bar{X}] &\approx \nu + \frac{\delta}{\mu} \nu (1 - \nu) (1 - Q_{\text{out}}^{\text{M}}) \times \\ &\quad \left[\underbrace{\left(\frac{(1 - \mu)(-c)}{(b - c) \left(\frac{\mu}{N} - \frac{1 - m}{n} \right)} \right)}_{-C^{\text{BD}}} + \underbrace{\left(\frac{(1 - \mu)b}{(b - c)(n - 1) \left(\frac{\mu}{N} - \frac{1 - m}{n} \right)} \right)}_{B^{\text{BD}}} \underbrace{\frac{Q_{\text{in}}^{\text{M}} - Q_{\text{out}}^{\text{M}}}{1 - Q_{\text{out}}^{\text{M}}}}_{R^{\text{M}}} \right], \end{aligned} \quad (\text{A26}) \quad \{\text{eq:EXBD}\}$$

732 In addition, for both Moran life-cycles, we have $B_{\text{M}}^* = 1/N$. The secondary ef-
733 fects (second line in the parentheses in eq. (A26)) include competitive effects

on the probability of reproducing, and consequences of social interactions on the probability that a given individual dies. Note that the secondary effects remain negative for the realistic range of emigration values that we consider (*i.e.*, $m < 1 - 1/N_D$).

Moran Death-Birth Under this life-cycle, we obtain {eq:dWDB}

$$\left. \frac{\partial W^{\text{DB}}}{\partial f_{\bullet}} \right|_{\delta=0} = \frac{1-\mu}{N} \left[1 - \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right) \right], \quad (\text{A27a})$$

$$\left. \frac{\partial W^{\text{DB}}}{\partial f_{\text{in}}} \right|_{\delta=0} = -\frac{1-\mu}{N} \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right). \quad (\text{A27b})$$

With the Death-Birth life-cycle, eq. (5) becomes

$$\mathbb{E}[\bar{X}] \approx \nu + \frac{\delta}{\mu} \nu (1-\nu) (1-Q_{\text{out}}^{\text{M}}) \times \left[\underbrace{\left(\frac{(1-\mu)(-c)}{-(b-c)(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right)} \right)}_{-\mathcal{C}^{\text{DB}}} + \underbrace{\left(\frac{(1-\mu)b}{-(b-c)(n-1)(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right)} \right)}_{\mathcal{B}^{\text{DB}}} \underbrace{\left(\frac{Q_{\text{in}}^{\text{M}} - Q_{\text{out}}^{\text{M}}}{1 - Q_{\text{out}}^{\text{M}}} \right)}_{R^{\text{M}}} \right], \quad (\text{A28}) \quad \{\text{eq:EXDB}\}$$

With this life-cycle, Death occurs first, and the probability of dying is independent from the state of the population (since we assume that social interactions affect fecundity. We can therefore factor $(1-\mu)$ in all terms. The primary effects (first lines in the parentheses) remain the same as with the Birth-Death life-cycle. However, the Death-Birth life-cycle leads to different secondary effects compared to the Birth-Death life-cycle: competition occurs at a different scale (Grafen & Archetti, 2008). Finally, with this life-cycle as we defined it, the probabilities of identity by descent Q are the same as with the Birth-Death model.

Wright-Fisher Under this life-cycle, we obtain {eq:dWWF}

$$\left. \frac{\partial W^{\text{WF}}}{\partial f_{\bullet}} \right|_{\delta=0} = (1-\mu) \left[1 - \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right) \right], \quad (\text{A29a})$$

$$\left. \frac{\partial W^{\text{WF}}}{\partial f_{\text{in}}} \right|_{\delta=0} = -(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right). \quad (\text{A29b})$$

749 For the Wright-Fisher life-cycle, we have $B_{\text{WF}}^* = 1$. Replacing the derivatives pre-
 750 sented in eq. (A29) into eq. (5), we obtain

$$\mathbb{E}[\bar{X}] \approx v + \frac{\delta}{\mu} v(1-v)(1-Q_{\text{out}}^{\text{WF}}) \times$$

$$\left[\underbrace{\left(\frac{(1-\mu)(-c)}{-(b-c)(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right)} \right)}_{-\mathcal{C}^{\text{WF}}} + \underbrace{\left(\frac{(1-\mu)b}{-(b-c)(n-1)(1-\mu) \left(\frac{(1-m)^2}{n} + \frac{m^2}{N-n} \right)} \right)}_{\mathcal{B}^{\text{WF}}} \underbrace{\left(\frac{Q_{\text{in}}^{\text{WF}} - Q_{\text{out}}^{\text{WF}}}{1 - Q_{\text{out}}^{\text{WF}}} \right)}_{R^{\text{WF}}} \right],$$

(A30) {eq:EXWF}

751 The only – but important – different between eq. (A30) and eq. (A28) is the value
 752 of the probabilities of identity by descent Q , because the number of individuals
 753 that are updated at each time step differs.

754 C Probabilities of identity by descent

755 C.1 Expected state of pairs of sites and probabilities of identity by de- 756 scent

{sec:app:IBD}

757 Here we show the link between the expected state of a pair of sites P_{ij} and prob-
758 abilities of identity by descent Q_{ij} . In our derivation of $\mathbb{E}[\bar{X}]$, P_{ij} is the quantity
759 that appears, but most studies use Q_{ij} . Both are evaluated in the absence of
760 selection ($\delta = 0$).

761 C.1.1 Moran model

762 In a Moran model, exactly one individual dies and one individual reproduces
763 during one time step. Given a state \mathbf{X} at time t , at time $t + 1$ both sites i and
764 $j \neq i$ are occupied by altruists, if i it was the case at time t and neither site was
765 replaced by a non-altruist (first term in eq. (A31)), or ij if exactly one of the two
766 sites was occupied by a non-altruist at time t , but the site was replaced by an
767 altruist (second and third terms of eq. (A31)):

$$\begin{aligned} \mathbb{E}[X_i X_j(t+1) | X(t) = \mathbf{X}] = & X_i X_j \left(1 - \sum_{k=1}^N \frac{1}{N} (d_{ki} + d_{kj}) ((1 - X_k)(1 - \mu) + \mu(1 - \nu)) \right) \\ & + X_i(1 - X_j) \sum_{k=1}^N \frac{1}{N} d_{kj} (X_k(1 - \mu) + \mu\nu) \\ & + X_j(1 - X_i) \sum_{k=1}^N \frac{1}{N} d_{ki} (X_k(1 - \mu) + \mu\nu). \end{aligned} \quad (\text{A31}) \quad \{\text{eq:app:Pi jM1}\}$$

768 We take the expectation of this quantity, and consider that the stationary dis-
769 tribution is reached ($t \rightarrow \infty$); then $\mathbb{E}[X_i X_j(t+1)] = \mathbb{E}[X_i X_j(t)]$, and we obtain

$$P_{ij} = \frac{1}{2} \left(\sum_{k=1}^N (1 - \mu) (d_{kj} P_{ki} + d_{ki} P_{kj}) \right) + \mu\nu^2 \quad (i \neq j), \quad (\text{A32}) \quad \{\text{eq:app:Pi jM}\}$$

770 while $P_{ii} = \nu$.

771 Now we substitute $P_{ij} = \nu^2 + \nu(1 - \nu)Q_{ij}$ in eq. (A32), we obtain

$$Q_{ij} = \frac{1}{2} \sum_{k=1}^N (1 - \mu) (d_{ki} Q_{kj} + d_{kj} Q_{ki}), \quad (\text{A33}) \quad \{\text{eq:app:Qi jM}\}$$

772 and we realize that Q_{ij} is the probability that the individuals at sites i and $j \neq i$
773 are identical by descent. To compute it indeed, we need to pick which site was
774 last updated (equal probabilities), then who was the parent (k); the other indi-
775 vidual needs to be identical by descent to the parent, and no mutation should
776 have occurred ($1 - \mu$).

777 C.1.2 Wright-Fisher model

778 In a Wright-Fisher model, all individuals are replaced at each time step, so we
779 directly consider the state of the parents:

$$\begin{aligned} \mathbb{E}[X_i X_j(t+1) | X(t) = \mathbf{X}] = & \sum_{k, \ell=1}^N d_{ki} d_{\ell j} \left(X_k X_\ell (1 - \mu + \mu v)^2 \right. \\ & + (X_k(1 - X_\ell) + (1 - X_k)X_\ell) (1 - \mu + \mu v)(\mu v) \\ & \left. + (1 - X_k)(1 - X_\ell)(\mu v)^2 \right) \end{aligned} \quad (A34) \quad \{\text{eq:app:Pi jWF1}\}$$

780 The first term of eq. (A34) corresponds to both parents being altruists, and hav-
781 ing altruist offspring; the second line corresponds to exactly one parent being
782 altruist, and the third line to both parents being non-altruists (in this latter case,
783 the two offspring have to be both mutants to be altruists).

784 Taking the expectation and simplifying, we obtain

$$P_{ij} = \sum_{k, \ell=1}^N (P_{kl}(1 - \mu)^2) + (2 - \mu)\mu v^2. \quad (A35) \quad \{\text{eq:app:Pi jWF}\}$$

785 Replacing P_{ij} by $v^2 + v(1 - v)Q_{ij}$, eq. (A35) becomes

$$Q_{ij} = \sum_{k, \ell=1}^N d_{ki} d_{\ell j} Q_{k\ell} (1 - \mu)^2. \quad (A36) \quad \{\text{eq:app:Qi jWF}\}$$

786 Again, Q_{ij} corresponds to a probability of identity by descent: the individuals at
787 sites i and j are identical by descent if their parents were and if neither mutated
788 $((1 - \mu)^2)$.

789 C.2 Probabilities of identity by descent in a subdivided population {sec:app:Qsubdiv}

790 Two individuals are said to be identical by descent if there has not been any mu-
 791 tation on either lineage since their common ancestor. Because of the structure
 792 of the population, there are only three types of pairs of individuals, and hence
 793 three different values of the probabilities of identity by descent of pairs of sites
 794 Q_{ij} :

$$Q_{ij} = \begin{cases} 1 & \text{when } i = j; \\ Q_{\text{in}} & \text{when } i \neq j \text{ and both sites are in the same deme;} \\ Q_{\text{out}} & \text{when sites } i \text{ and } j \text{ are in different demes.} \end{cases} \quad (\text{A37})$$

795 The values of Q_{in} and Q_{out} depend on the type of life-cycle that we consider.

796 Here, we will use formulas derived in Débarre (2017) for “two-dimensional
 797 population structures”. The name comes from the fact that we only need two
 798 types of transformations to go from any site to any other site in the population:
 799 permutations on the deme index, and permutations on the within-deme index.
 800 We rewrite site labels ($1 \leq i \leq N$) as (ℓ_1, ℓ_2) , where ℓ_1 is the index of the deme ($1 \leq$
 801 $\ell_1 \leq N_D$) and ℓ_2 the position of the site within the deme ($1 \leq \ell_2 \leq n$). Then, we
 802 introduce notations \tilde{d}_{i_1, i_2} and \tilde{Q}_{i_1, i_2} , that correspond to the dispersal probability and
 803 probability of identity by descent to a site at distances i_1 and i_2 in the among-
 804 demes and within-deme dimensions (e.g., $\tilde{d}_{i_1, i_2} = d_{j_1, j_2'}$ where $j_1 = i_1$ and $j_2' = i_2$).

805 Also, in this section, we distinguish between $d_{\text{self}} = d_{ii}$ and d_{in} (in the main
 806 text, $d_{\text{self}} = d_{\text{in}}$).

807 C.2.1 Moran model

808 In Débarre (2017), it was shown that

$$\tilde{Q}_{r_1, r_2} = \frac{1}{N} \sum_{q_1=0}^{N_1-1} \sum_{q_2=0}^{N_2-1} \frac{\mu \lambda'_M}{1 - (1 - \mu) \tilde{D}_{q_1, q_2}} \exp\left(i \frac{2\pi q_1 r_1}{N_1}\right) \exp\left(i \frac{2\pi q_2 r_2}{N_2}\right) \quad (\text{A38a}) \quad \{\text{eq:app:Q2DM}\}$$

809 with

$$\tilde{D}_{q_1, q_2} = \sum_{\ell_1=0}^{N_1-1} \sum_{\ell_2=0}^{N_2-1} \tilde{d}_{\ell_1, \ell_2} \exp\left(-i \frac{2\pi q_1 \ell_1}{N_1}\right) \exp\left(-i \frac{2\pi q_2 \ell_2}{N_2}\right), \quad (\text{A38b}) \quad \{\text{eq:app:D2D}\}$$

810 and λ'_M such that $\tilde{Q}_0 = 1$. Let us first compute \tilde{D}_{q_1, q_2} in the case of a subdivided
 811 population, with $N_1 = N_D$ and $N_2 = n$:

$$\begin{aligned} \tilde{D}_{q_1, q_2} &= d_{\text{self}} + \sum_{\ell_2=1}^{N_2-1} d_{\text{in}} \exp\left(-i \frac{2\pi q_2 \ell_2}{N_2}\right) + \sum_{\ell_1=1}^{N_1-1} \sum_{\ell_2=0}^{N_2-1} d_{\text{out}} \exp\left(-i \frac{2\pi q_1 \ell_1}{N_1}\right) \exp\left(-i \frac{2\pi q_2 \ell_2}{N_2}\right) \\ &= d_{\text{self}} + (\delta_{q_2} (N_2 - 1) + (1 - \delta_{q_2}) (-1)) d_{\text{in}} + (\delta_{q_1} (N_1 - 1) + (1 - \delta_{q_1}) (-1)) (\delta_{q_2} N_2) d_{\text{out}} \\ &= d_{\text{self}} + (\delta_{q_2} N_2 - 1) d_{\text{in}} + (\delta_{q_1} N_1 - 1) \delta_{q_2} N_2 d_{\text{out}}. \end{aligned} \quad (\text{A39a})$$

812 (δ_q is equal to 1 when q is equal to 0 modulo the relevant dimension, and to 0
 813 otherwise). So for the three types of distances that we need to consider (distance
 814 0, distance to another deme-mate, distance to individual in another deme), and
 815 with $N_1 = N_D$ and $N_2 = n$, we obtain

{eq:app:Dsystem}

$$\tilde{D}_0 = 1, \quad (\text{A40a})$$

$$\tilde{D}_{q_1} = 1 - m - \frac{m}{N_D - 1} \quad (q_1 \not\equiv 0 \pmod{N_1}), \quad (\text{A40b})$$

$$\tilde{D}_{q_1} = d_{\text{self}} - d_{\text{in}} \quad (q_2 \not\equiv 0 \pmod{N_2}). \quad (\text{A40c})$$

816 So for \tilde{Q} , using system (A40) in eq. (A38a),

$$\begin{aligned} \tilde{Q}_{r_1} &= \frac{\mu \lambda'_M}{N} \left[\frac{1}{1 - (1 - \mu) \tilde{D}_0} + \sum_{q_2=1}^{N_2-1} \frac{1}{1 - (1 - \mu) \tilde{D}_{q_2}} \exp\left(-\iota \frac{2\pi q_2 r_2}{N_2}\right) \right. \\ &\quad + \sum_{q_1=1}^{N_1-1} \frac{1}{1 - (1 - \mu) \tilde{D}_{q_1}} \exp\left(-\iota \frac{2\pi q_1 r_1}{N_1}\right) \\ &\quad \left. + \sum_{q_1=1}^{N_1-1} \sum_{q_2=1}^{N_2-1} \frac{1}{1 - (1 - \mu) \tilde{D}_{q_1}} \exp\left(-\iota \frac{2\pi q_1 r_1}{N_1}\right) \exp\left(-\iota \frac{2\pi q_2 r_2}{N_2}\right) \right] \\ &= \frac{\mu \lambda'_M}{N} \left[\frac{1}{1 - (1 - \mu)} + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (\delta_{r_2} N_2 - 1) \right. \\ &\quad + \frac{1}{1 - (1 - \mu)(1 - m - \frac{m}{N_D - 1})} (\delta_{r_1} N_1 - 1) \\ &\quad \left. + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (\delta_{r_1} N_1 - 1)(\delta_{r_2} N_2 - 1) \right]. \quad (\text{A41}) \quad \{\text{eq:app:Q2DMsol}\} \end{aligned}$$

817 In particular,

$$\begin{aligned} \tilde{Q}_0 &= \frac{\mu \lambda'_M}{N} \left[\frac{1}{\mu} + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (n - 1) + \frac{1}{1 - (1 - \mu)(1 - m - \frac{m}{N_D - 1})} (N_D - 1) \right. \\ &\quad \left. + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (N_D - 1)(n - 1) \right] \\ &= 1. \quad (\text{A42a}) \quad \{\text{eq:app:Q2D1}\} \end{aligned}$$

818 We find λ'_M using eq. (A42a). Let's now go back to eq. (A41): when $r_1 = 0$, the two
 819 individuals are in the same deme. They are different when $r_2 \neq 0$, and so:

$$\begin{aligned} Q_{\text{in}} &= \frac{\mu \lambda'_M}{N} \left[\frac{1}{\mu} + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (-1) + \frac{1}{1 - (1 - \mu)(1 - m - \frac{m}{N_D - 1})} (D - 1) \right. \\ &\quad \left. + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} (D - 1)(-1) \right]. \quad (\text{A42b}) \end{aligned}$$

820 And when $r_1 \neq 0$, the two individuals are in different demes:

$$Q_{\text{out}} = \frac{\mu \lambda'_M}{N} \left[\frac{1}{\mu} + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})}(-1) + \frac{1}{1 - (1 - \mu)(1 - m - \frac{m}{N_D - 1})}(-1) + \frac{1}{1 - (1 - \mu)(d_{\text{self}} - d_{\text{in}})} \right]. \quad (\text{A42c})$$

821 With $d_{\text{self}} = d_{\text{in}} = (1 - m)/n$, we eventually obtain:

{eq:QM}

$$Q_{\text{in}}^M = \frac{(1 - \mu)(m + \mu(N_D(1 - m) - 1))}{(1 - \mu)m(N_D\mu(n - 1) + 1) + (N_D - 1)\mu(\mu(n - 1) + 1)}, \quad (\text{A43a})$$

$$Q_{\text{out}}^M = \frac{(1 - \mu)m}{(1 - \mu)m(N_D\mu(n - 1) + 1) + (N_D - 1)\mu(\mu(n - 1) + 1)}. \quad (\text{A43b})$$

822 The probability that two different deme-mates are identical by descent, Q_{in}^M , de-
823 creases monotonically with the emigration probability m , while Q_{out}^M monoton-
824 ically increases with m (see figure A5(a)).

825 When the mutation probability μ is vanishingly small ($\mu \rightarrow 0$), both Q_{in}^M and
826 Q_{out}^M are equal to 1: in the absence of mutation indeed, the population ends up
827 fixed for one of the two types, and all individuals are identical by descent. Note
828 that we obtain a different result if we first assumed that the size of the popu-
829 lation is infinite ($N_D \rightarrow \infty$), because the order of limits matters; for instance,
830 $\lim_{N_D \rightarrow \infty} Q_{\text{out}}^M = 0$.

831 Using eq. (A43), relatedness under the Moran model is given by

$$R^M = \frac{(1 - \mu)(N_D(1 - m) - 1)}{N_D(1 - \mu)m(n - 1) + (N_D - 1)(1 + \mu(n - 1))}. \quad (\text{A44}) \quad \{\text{eq:app:RM}\}$$

832 When there is an infinite number of demes ($N_D \rightarrow \infty$) and mutation is vanish-
833 ingly small ($\mu \rightarrow 0$), we recover

$$\lim_{\mu \rightarrow 0} \lim_{N_D \rightarrow \infty} R^M = \lim_{N_D \rightarrow \infty} \lim_{\mu \rightarrow 0} R^M = \frac{1 - m}{1 + m(n - 1)}. \quad (\text{A45}) \quad \{\text{eq:app:RMLim}\}$$

834 C.2.2 Wright-Fisher

835 For the Wright-Fisher updating, the equation for \tilde{Q} is different:

$$\tilde{Q}_{r_1 r_2} = \frac{1}{N} \sum_{q_1=0}^{N_1-1} \sum_{q_2=0}^{N_2-1} \frac{\mu \lambda'_{WF}}{1 - (1 - \mu)^2 (\tilde{D}_{q_1})^2} \exp\left(-i \frac{2\pi q_1 r_1}{N_1}\right) \exp\left(-i \frac{2\pi q_2 r_2}{N_2}\right), \quad (\text{A46})$$

836 with $\tilde{\mathcal{D}}$ given in eq. (A38b). In a subdivided population, with $N_1 = N_D$ and $N_2 = n$,
 837 this becomes

$$\begin{aligned}
 \tilde{Q}_{r_1 r_2} &= \frac{1}{N} \left[\frac{\mu \lambda'_{WF}}{1 - (1 - \mu)^2 (\tilde{\mathcal{D}}_0)^2} + \sum_{q_2=1}^{N_2-1} \frac{\mu \lambda'_{WF}}{1 - (1 - \mu)^2 (\tilde{\mathcal{D}}_{q_2})^2} \exp\left(-i \frac{2\pi q_2 r_2}{N_2}\right) \right. \\
 &\quad + \sum_{q_1=1}^{N_1-1} \frac{\mu \lambda'_{WF}}{1 - (1 - \mu)^2 (\tilde{\mathcal{D}}_{q_1})^2} \exp\left(-i \frac{2\pi q_1 r_1}{N_1}\right) \\
 &\quad \left. + \sum_{q_1=1}^{N_1-1} \sum_{q_2=1}^{N_2-1} \frac{\mu \lambda'_{WF}}{1 - (1 - \mu)^2 (\tilde{\mathcal{D}}_{q_1})^2} \exp\left(-i \frac{2\pi q_1 r_1}{N_1}\right) \exp\left(-i \frac{2\pi q_2 r_2}{N_2}\right) \right] \\
 &= \frac{\mu \lambda'_{WF}}{N} \left[\frac{1}{1 - (1 - \mu)^2} + \frac{1}{1 - (1 - \mu)^2 (d_{\text{self}} - d_{\text{in}})^2} (\delta_{q_2} N_2 - 1) \right. \\
 &\quad + \frac{1}{1 - (1 - \mu)^2 (1 - m - \frac{m}{N_D-1})^2} (\delta_{q_1} N_1 - 1) \\
 &\quad \left. + \frac{1}{1 - (1 - \mu)^2 (d_{\text{self}} - d_{\text{in}})^2} (\delta_{q_1} N_1 - 1) (\delta_{q_2} N_2 - 1) \right] \\
 &= \frac{\mu \lambda'_{WF}}{N} \left[\frac{1}{1 - (1 - \mu)^2} + \frac{1}{1 - (1 - \mu)^2 (d_{\text{self}} - d_{\text{in}})^2} (\delta_{q_2} N_2 - 1) \delta_{q_1} N_1 \right. \\
 &\quad \left. + \frac{1}{1 - (1 - \mu)^2 (1 - m - \frac{m}{N_D-1})^2} (\delta_{q_1} N_1 - 1) \right]. \tag{A47} \quad \{\text{eq:app:Q2DWFsol}\}
 \end{aligned}$$

838 To find λ'_{WF} , we solve $\tilde{Q}_0 = 1$, i.e.,

$$1 = \frac{\mu \lambda'_{WF}}{N} \left[\frac{1}{1 - (1 - \mu)^2} + \frac{1}{1 - (1 - \mu)^2 (d_{\text{self}} - d_{\text{in}})^2} (N_2 - 1) N_1 + \frac{1}{1 - (1 - \mu)^2 (1 - m - \frac{m}{N_D-1})^2} (N_1 - 1) \right]. \tag{A48a}$$

839 Then from eq. (A47) we deduce

$$Q_{\text{in}} = \frac{\mu \lambda'_{WF}}{N} \left[\frac{1}{1 - (1 - \mu)^2} - \frac{1}{1 - (1 - \mu)^2 (d_{\text{self}} - d_{\text{in}})^2} N_1 + \frac{1}{1 - (1 - \mu)^2 (1 - m - \frac{m}{N_D-1})^2} (N_1 - 1) \right]. \tag{A48b}$$

840 and

$$Q_{\text{out}} = \frac{\mu \lambda'_{WF}}{N} \left[\frac{1}{1 - (1 - \mu)^2} - \frac{1}{1 - (1 - \mu)^2 (1 - m - \frac{m}{d-1})^2} \right]. \tag{A48c}$$

841 With $d_{\text{self}} = d_{\text{in}} = (1 - m)/n$, we obtain:

{eq:QWF}

$$Q_{\text{in}}^{\text{WF}} = \frac{-N_D + M_1 + M_2}{(n - 1)N_D + M_1 + M_2}, \tag{A49a}$$

$$Q_{\text{out}}^{\text{WF}} = \frac{-\frac{1}{N_D-1} M_1 + M_2}{(n - 1)N_D + M_1 + M_2}, \tag{A49b}$$

842 with

$$M_1 = \frac{N_D - 1}{1 - \frac{(1 - \mu)^2 (N_D (1 - m) - 1)^2}{(N_D - 1)^2}} \text{ and } M_2 = \frac{1}{1 - (1 - \mu)^2}.$$

(These formulas are compatible with, *e.g.*, results presented by Cockerham & Weir (1987), adapted for haploid individuals).

In the Wright-Fisher life-cycle, $Q_{\text{in}}^{\text{WF}}$ decreases until $m = m_c^{\text{WF}} = \frac{N_D - 1}{N_D}$, while $Q_{\text{out}}^{\text{WF}}$ follows the opposite pattern. The threshold value m_c^{WF} corresponds to an emigration probability so high that $d_{\text{in}} = d_{\text{out}}$.

The two probabilities of identity by descent go to 1 when the mutation probability μ is very small ($\mu \rightarrow 0$), except if we first assume that the number of demes is very large ($N_D \rightarrow \infty$); for instance, with this life-cycle as well, $\lim_{N_D \rightarrow \infty} Q_{\text{out}}^{\text{WF}} = 0$.

Also, because more sites (all of them, actually) are updated at each time step, Q_{in} is lower for the Wright-Fisher updating than for a Moran updating, under which only one site is updated at each time step (compare figure A5(a) and A5(b)).

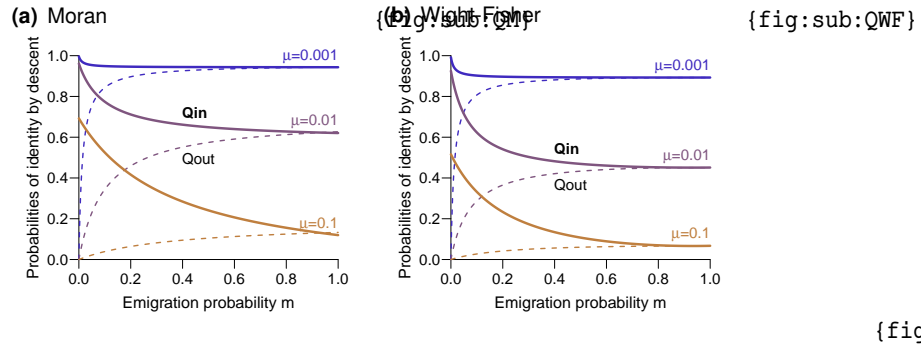

Figure A5: Probabilities of identity by descent, for two different individuals within the same deme (Q_{in} , full curves) and two individuals in different demes (Q_{out} , dashed curves), as a function of the emigration probability m , for different values of the mutation probability μ (0.001, 0.01, 0.1), and for the two types of life-cycles ((a): Moran, (b): Wright-Fisher). Other parameters: $n = 4$ individuals per deme, $N_D = 15$ demes.

Combining the formulas presented in eq. (A49), we obtain

$$R^{\text{WF}} = \frac{(1 - N_D(1 - m))^2(1 - \mu)^2}{D^{\text{WF}}}, \quad (\text{A50}) \quad \{\text{eq:app:RWF}\}$$

with

$$D^{\text{WF}} = 1 - N_D(2(1 + m(n - 1)) - N_D(1 + (2 - m)m(n - 1))) - 2\mu + 2(N_D(N_D(1 - m) - 2)(1 - m)(n - 1) + n)\mu - (1 - N_D(1 - m))^2(n - 1)\mu^2.$$

When the number of demes is very large and mutation is vanishingly small,

859 eq. (A50) reduces to

$$\lim_{\mu \rightarrow 0} \lim_{N_D \rightarrow \infty} R^{\text{WF}} = \lim_{N_D \rightarrow \infty} \lim_{\mu \rightarrow 0} R^{\text{WF}} = \frac{(1-m)^2}{1 + (2-m)m(n-1)}. \quad (\text{A51}) \quad \{\text{eq:app:RWFlim}\}$$
